### 1.4.1 Faroe Plateau cod (Subdivision Vb $\mathbf{1}_{1}$ )

## State of the stock

| Spawning biomass <br> in relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> highest yield | Fishing <br> mortality in <br> relation to <br> agreed target | Comment |
| :--- | :--- | :--- | :--- | :--- |
| Increased risk | Harvested <br> unsustainably | Overexploited | Above <br> agreed target |  |

Based on the most recent estimates of SSB, ICES classifies the stock as being at risk of reduced reproductive capacity. SSB in 2005 is on the same level as prior to the collapse in 1990. Based on the most recent estimates of fishing mortality ICES classifies the stock as being harvested unsustainably. The estimate of fishing mortality has been above the proposed $\mathbf{F}_{\mathrm{pa}}$ since 1996. The spawning stock biomass was well above $\mathbf{B}_{\mathrm{pa}}$ for several years, but has been below $\mathbf{B}_{\mathrm{pa}}$ since 2004. The recruitment after the 2000 year class has been at or below average

## Management objectives

The management objective is to achieve sustainable fisheries. An effort management system was implemented in the Faroese demersal fisheries in Division Vb in 1996. From the outset the aim of the effort management system was to harvest on average $33 \%$ in numbers of the exploitable stock of cod. This translates into an average F of approximately 0.45 , above the $\mathbf{F}_{\mathrm{pa}}$ of 0.35 . ICES considers this to be inconsistent with the Precautionary Approach

## Reference points

|  | ICES considers that: | ICES proposed that: |
| :--- | :--- | :--- |
| Precautionary Approach <br> reference points | $\mathbf{B}_{\mathrm{lim}}$ is 21000 t | $\mathbf{B}_{\mathrm{pa}}$ be set at 40000 t |
|  | $\mathbf{F}_{\text {lim }}$ is 0.68 | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.35 |

Technical basis

| $\mathbf{B}_{\text {lim }}: \mathbf{B}_{\text {lim }}=\mathbf{B}_{\text {loss }}(98)$ | $\mathbf{B}_{\mathrm{pa}}: \mathbf{B}_{\mathrm{pa}}=\mathbf{B}_{\text {lim }} \mathrm{e}^{1.645 \sigma}$, assuming a $\sigma$ of about 0.40 to account <br> for the relatively large uncertainties in the assessment |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}: \mathbf{F}_{\text {lim }}=\mathbf{F}_{\mathrm{pa}} \mathrm{e}^{1.645 \sigma}$, assuming a $\sigma$ of about 0.40 to <br> account for the relatively large uncertainties in the <br> assessment | $\mathbf{F}_{\mathrm{pa}}:$ Close to $\mathbf{F}_{\text {max }}(0.34)$ and $\mathbf{F}_{\text {med }}(0.38)$ values from 1998 <br> assessment |

Yield and spawning biomass per Recruit

| $\mathbf{F}_{\text {med }}$ | 0.38 | 1.36 | 4.20 |

## Single-stock exploitation boundaries

## Exploitation boundaries in relation to existing management plans

The management objective implied in the effort management scheme is to achieve an average exploitation rate equivalent to a fishing mortality of 0.45 . Assuming proportionality between effort and F and adherence to the management plan would imply a reduction in effort of more than $40 \%$ compared to the average F of the last 3 years.

Exploitation boundaries in relation to high long-term yield, low risk of depletion of production potential and considering ecosystem effects

The current fishing mortality estimated as 0.75 is above rates that would support optimal long-term yield and low risk of stock depletion ( $\mathbf{F}_{0.1}=0.25$ and $\mathbf{F}_{\max }=0.46$ ).

## Exploitation boundaries in relation to precautionary limits

Rebuilding SSB to above $\mathbf{B}_{\mathrm{pa}}$ in one year will require closing all directed cod fisheries in 2006. Rebuilding SSB over a longer period will require a rebuilding plan.

Such a rebuilding plan should at least result in a fishing mortality below $\mathbf{F}_{\mathrm{pa}}$. This would amount to an effort reduction of about $50 \%$ compared to the recent level.

## Short-term implications

Outlook for 2006
Basis: $\mathrm{F}(2005)=0.75 ; \operatorname{SSB}(2006)=26$; catch $(2005)=17$.
The fishing mortality according to the management plan ( F (management plan)) is 0.45 .
The maximum fishing mortality which would be in accordance with precautionary limits ( F (precautionary limits)) is 0.35 .

${ }^{1)}$ SSB 2007 relative to SSB 2006.

## Management considerations

An expected benefit of the effort management system was more stability for the fishing fleet. The fleets were expected to target the most abundant fish species (cod, haddock, or saithe), thus reducing the fishing mortality on stocks being in
a bad shape. However, low prices on saithe and haddock and high prices for cod have kept the fishing mortality high on cod. Targeting of cod appears to be more influenced by economic factors than relative abundance of the stocks.

## Management plan evaluations

The effort management system translates to an average $F$ of 0.45 . The management plan has not been fully evaluated by ICES in relation to the defined $\mathbf{B}_{\text {lim }}$. A full evaluation should take into account the relationship between fishing mortality and fishing days.

## Ecosystem considerations

The effort management system needs to consider changes in catchability of the fishery. For baited hook gear, catchability is related to the amount of food available in the ecosystem. Therefore, low ecosystem production may decrease cod production and increase the catchability of longline gear. Primary productivity of the Faroe ecosystem in 2005 appears to be about average but may vary by a factor of five and has profound effects on fish stocks. Extended periods of low ecosystem production may require a reconsideration of the effort management system and a shift to catch-based management.

The productivity of the Faroe Shelf ecosystem has been shown to be of ultimate importance to the cod stock (Steingrund and Gaard, 2005). The index of primary production was considerably higher in 2004 than in 1990-1992, which may prevent a collapse in the fishery in the near future. The fishing mortality in 2004 was, however, very high when the low stock size is taken into account. Under the present fishing mortality, normal catches in the near future can only be achieved if the environmental conditions are favourable.

## Factors affecting the fisheries and the stock

## Regulations and their effects

An effort management system was implemented $1^{\text {st }}$ of June 1996. Fishing days are allocated to all fleets fishing in shallow waters (<380-m depth) for the period 1 September-31 August. In addition the majority of the shallow areas ( < ca. 200 m ) are closed for trawling, and are mainly utilised by longliners. The main spawning areas for cod are closed for nearly all fishing gears during spawning time.

## Changes in fishing technology and fishing patterns

The effort management system invites improvement of fishing technology and fishing patterns. Some improvements were evident just after the introduction of the system, but no major improvements have been evident in subsequent years.

## Scientific basis

## Data and methods

The stock is assessed by an analytical method using survey and catch-at-age data. The technique was the same as the one used for last year's assessment, XSA calibrated by two research surveys.

The reference fishing mortality is based on a simple average of age group 3 to 7. In some years the fishing mortality of a particular age group may be unduly high and may more reflect sampling error rather than fishing mortality rates. Using a different basis for calculating reference F gives a different indication of the exploitation of this stock. However, this would require a re-evaluation of the F reference points.

## Comparison with previous assessment and advice

The present assessment confirms the increase in fishing mortality in recent years. In last year's assessment the 2004 SSB and F were estimated at 30000 t and 0.99 , respectively. This year's estimate of the 2004 SSB and F are 34000 t and 0.79.
