### 1.4.4 Faroe saithe in Division Vb

## State of the stock

| Spawning <br> biomass in <br> relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> highest yield | Fishing mortality in <br> relation to agreed <br> target | Comment |
| :--- | :--- | :--- | :--- | :--- |
| Increased risk | Harvested <br> unsustainably | Overexploited | Below agreed target |  |

Based on the most recent estimates of SSB and fishing mortality, ICES classifies the stock as being at risk of reduced reproductive capacity and to be harvested unsustainably.

The estimate of fishing mortality has been above the proposed $\mathbf{F}_{\text {lim }}$ since 2000. The spawning stock biomass has been below $\mathbf{B}_{\mathrm{pa}}$ since 2001. Recruitment of the 1996 to 2000 year classes was above average, including the strong 1998 year class. The estimation of the 2001 year class is uncertain but is presently estimated to be record low.

## Management objectives

The management objective is to achieve sustainable fisheries. An effort management system was implemented in the Faroese demersal fisheries (Division Vb ) in 1996 and aims at harvesting, on average, $33 \%$ of the saithe stock in numbers. This translates into an average F of 0.45 , above the $\mathbf{F}_{\mathrm{pa}}$ of 0.28 . ICES considers this F level to be inconsistent with the Precautionary Approach.

Reference points

|  | ICES considers that: | ICES proposed that: |
| :--- | :--- | :--- |
| Precautionary Approach reference points | $\mathbf{B}_{\text {lim }}$ is 60000 t | $\mathbf{B}_{\mathrm{pa}}$ be set at 85000 t |
|  | $\mathbf{F}_{\text {lim }}$ is 0.40 | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.28 |

## Technical basis

$\mathbf{B}_{\lim }$ : lowest observed SSB established in 1999 and corresponding to $\mathbf{B}_{\mathrm{pa}}$ : former MBAL
SSB in 1992
$\mathbf{F}_{\text {lim }}$ : consistent with $\mathbf{B}_{\text {lim }}$ of $60000 \mathrm{t} \quad \mathrm{F}_{\mathrm{pa}}$ :consistent with $\mathbf{F}_{\text {lim }}$ of $\mathbf{F}_{\text {med }}$ and previous estimate

## Yield and spawning biomass per Recruit

F-reference points:

|  | Fish Mort <br> Ages 4-8 | Yield/R | SSB/R |
| :--- | :---: | :---: | :---: |
| Average last 3 years | 0.459 | 1.530 | 3.088 |
| $\mathbf{F}_{0.1}$ | 0.119 | 1.323 | 7.773 |
| $\mathbf{F}_{\text {med }}$ | 0.363 | 1.529 | 3.684 |

## Single-stock exploitation boundaries

## Exploitation boundaries in relation to existing management plans

The current F is estimated to be around the management target of $\mathrm{F}=0.45$. The average fishing mortality for the period when this effort regulation scheme has been operative (1997-2004) is estimated at 0.40 per year. The agreed management plan implies no change in fishing mortality for 2006.

Exploitation boundaries in relation to high long-term yield, low risk of depletion of production potential and considering ecosystem effects

The current fishing mortality estimated as 0.44 is above rates that would support optimal long-term yield and low risk of stock depletion $\left(\mathbf{F}_{01}=0.119\right)$.

## Exploitation boundaries in relation to precautionary limits

Fishing effort in 2006 should be reduced to correspond to a fishing mortality below $\mathbf{F}_{\mathrm{pa}}=0.28$, corresponding to an effort reduction of about $40 \%$ if the relationship between fishing effort and fishing mortality is linear.

## Short-term implications

## Outlook for 2006

Basis: $\mathrm{F}(2005)=0.4585 ; \operatorname{SSB}(2006)=65$; catch $(2005)=45$.
The fishing mortality applied according to the agreed management plan ( F (management plan)) is 0.45 .
The maximum fishing mortality which would be in accordance with precautionary limits ( F (precautionary limits)) is 0.28 .

Weights in ' 000 t .
Shaded scenarios are not considered consistent with the Precautionary Approach.
${ }^{1)}$ SSB 2007 relative to SSB 2006.

## Management considerations

Maintaining the status quo fishing mortality implies that SSB is forecasted to be below $\mathbf{B}_{\mathrm{lim}}$ in 2007.

Saithe is mainly taken in a targeted pair trawl fishery in the deeper parts of the plateau. Due to the higher prices of cod there are incentives to increase cod bycatches.

Given the high fishing mortality and low stock size, the present spawning closures should be maintained.

## Management plan evaluations

The effort management system translates to an average F of 0.45 . The management plan has not been fully evaluated by ICES in relation to the defined $\mathbf{B}_{\text {lim }}$. A full evaluation should take into account the relationship between fishing mortality and fishing days.

## Ecosystem considerations

Blue whiting is a forage species for saithe. A proportion of the saithe stock is far off the shelf, probably preying on blue whiting. The blue whiting fishery thus also affects saithe by removing blue whiting.

## Factors affecting the fisheries and the stock

## Regulations and their effects

Limited measurements in the blue whiting fishery in Faroe waters indicate that bycatch of saithe may be significant. In order to get a reasonable estimate sampling is required on the blue whiting fishery.

## Changes in fishing technology and fishing patterns

Development in gear technology and optimizing fishing operations has resulted in an increase in the catchability since the early 1990s, preliminarily estimated in the order of $20 \%$ in the last decade.

## Scientific basis

## Data and methods

The stock assessment is an analytical assessment using commercial catch-at-age data and commercial (pair trawler) catch and standardized effort data from logbooks. In the present assessment the commercial CPUE that has been used for tuning has been standardized, taking into account season, fishing area, and boat factors.

There are no recruitment indices available for ages younger than 3 in the terminal year. Existing research surveys may be of use in tuning, but this has not been fully evaluated.

## Comparison with previous assessment and advice

Due to revised assessment data, the present estimate of fishing mortality in 2003 is $13 \%$ higher than estimated last year. SSB for 2004 is $36 \%$ lower than estimated in last year's assessment. This decline in SSB estimates is largely attributed to the observation of maturity-at-age and weight-at-age being lower than predicted last year.
