### 4.4.1 Faroe Plateau cod (Subdivision $\mathbf{V b}_{1}$ )

## State of the stock

| Spawning biomass <br> in relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> precautionary <br> limits | Fishing <br> mortality in <br> relation to <br> highest yield | Fishing <br> mortality in <br> relation to <br> agreed target | Comment |
| :--- | :--- | :--- | :--- | :--- |
| Increased risk | Increased risk | Overexploited | Appropriate |  |

Based on the most recent estimates of SSB, ICES classifies the stock as being at risk of reduced reproductive capacity. SSB in 2006 is at the same level as prior to the collapse in 1990. Based on the most recent estimates of fishing mortality, ICES classifies the stock as being at risk of being harvested unsustainably (Figure 4.4.1.3). The estimate of fishing mortality has been above the proposed $\mathbf{F}_{\mathrm{pa}}$ since 1996. Historically, the spawning stock biomass had been well above $\mathbf{B}_{\mathrm{pa}}$ for a number of the early years in the time-series, but has been below $\mathbf{B}_{\mathrm{pa}}$ since 2004. The recruitment after the 2000 year class has been at or below average.

## Management objectives

The management objective is to achieve sustainable fisheries. An effort management system was implemented in the Faroese demersal fisheries in Division Vb in 1996. From the outset the aim of the effort management system was to harvest on average $33 \%$ in numbers of the exploitable stock of cod. This translates into an average F of approximately 0.45 , above the $\mathbf{F}_{\mathrm{pa}}$ of 0.35 . ICES considers this to be inconsistent with the Precautionary Approach.

## Single-stock exploitation boundaries

## Exploitation boundaries in relation to existing management plans

The management objective implied in the effort management scheme is to achieve an average exploitation rate equivalent to a fishing mortality of 0.45 , compared to the current estimate 0.46 in 2005. Assuming proportionality between effort and F and adherence to the management plan would imply no change in effort for 2007.

Exploitation boundaries in relation to high long-term yield, low risk of depletion of production potential and considering ecosystem effects

The current fishing mortality estimated as 0.46 is above rates that would support optimal long-term yield and low risk of stock depletion ( $\mathbf{F}_{0.1}$ and $\mathbf{F}_{\text {max }}$ ).

## Exploitation boundaries in relation to precautionary limits

In the short term a reduction of $50 \%$ in fishing mortality in 2007 is required to rebuild this stock above $\mathbf{B}_{\mathrm{pa}}(=40000 \mathrm{t})$. The present management system has led to fishing mortalities that do not appear sustainable. ICES recommends a rebuilding plan including an adaptive approach on fishing effort and monitoring the development of the stock with reference to rebuilding to above $\mathbf{B}_{\mathrm{pa}}$. The reduction in fishing effort in 2007 should be in the order of $25 \%$ which corresponds to fishing at $\mathbf{F}_{\mathrm{pa}}$.

## Short-term implications

Outlook for 2007
Basis: $\mathrm{F}(2006)=0.46 ; \operatorname{SSB}(2007)=30$; catch $(2006)=12$.
The fishing mortality according to the management plan ( F (management plan)) is 0.45 .
The maximum fishing mortality which would be in accordance with precautionary limits ( F (precautionary limits)) is 0.35 .

Weights in ' 000 t. Shaded scenarios are not considered consistent with the Precautionary Approach.
${ }^{1)}$ SSB 2008 relative to SSB 2007.

## Management considerations

An expected benefit of the effort management system was more stability for the fishing fleet. The fleets were expected to target the most abundant fish species, thus reducing the fishing mortality on stocks that are in bad shape. However, low prices on saithe and haddock and high prices for cod have kept the fishing mortality high on cod. Targeting of cod
appears to be more influenced by economic factors than relative abundance of the stocks. Management should include measures that avoid a disproportionate targeting of depleted stocks.

## Management plan evaluations

The effort management system translates to an average F of 0.45 . Preliminary analyses by ICES indicate that there is a low probability that the SSB will fall below $\mathbf{B}_{\text {lim }}$ in the long term with this F , but a full evaluation needs to be undertaken that incorporates the relationship between fishing mortality and fishing days.

## Ecosystem considerations

The effort management system needs to consider changes in catchability of the fishery. For baited hook gear, catchability is related to the amount of food available in the ecosystem. Therefore, low ecosystem production may decrease cod production and increase the catchability of longline gear. Since the majority of cod catches are taken by longlines, fishing mortality will increase. Primary productivity of the Faroe ecosystem in 2006 appears to be about average, but may vary by a factor of five which has profound effects on fish stocks. Extended periods of low ecosystem production may require a reconsideration of the effort management system.

The productivity of the Faroe Shelf ecosystem has been shown to be of ultimate importance to the cod stock (Steingrund and Gaard, 2005). The spawning stock biomass depends heavily upon the recruitment which in turn depends heavily upon the productive state of the Faroe Shelf ecosystem. The index of primary production was low in 2002, 2003, and 2005, above average in 2004, and appears to be about average in 2006; the final estimate of the primary production will, however, not be available until late June. In order to get a recovery of the cod stock in the near future the productive state of the Faroe Shelf ecosystem must improve considerably in 2006 and 2007.

## Factors affecting the fisheries and the stock

## Regulations and their effects

An effort management system was implemented $1^{\text {st }}$ of June 1996. Fishing days are allocated to all fleets fishing in shallow waters (<380-m depth) for the period 1 September-31 August. In addition the majority of the shallow areas ( $<\mathrm{ca} .200 \mathrm{~m}$ ) are closed for trawling, and are mainly utilised by longliners. The main spawning areas for cod are closed for nearly all fishing gears during spawning time.

## Changes in fishing technology and fishing patterns

The effort management system invites improvement of fishing technology and fishing patterns. Some improvements were evident just after the introduction of the system, but no major improvements have been evident in subsequent years.

## Scientific basis

## Data and methods

The stock is assessed by an analytical method using survey and catch-at-age data. The technique was the same as the one used for last year's assessment, XSA calibrated by two research surveys. The Faroese catches on the Faroe-Iceland ridge, within the Vb 1 area, were removed from the current assessment for the years 1999-2005. This was done because evaluation of tagging data indicated that the cod fished in this area was more likely to be of Icelandic origin than Faroese.

## Comparison with previous assessment and advice

This year's assessment confirms the recent trends in fishing mortality and SSB. The advice is consistent with that in previous years.
