### 4.4.4 Faroe saithe in Division Vb

## State of the stock

The available information is inadequate to evaluate stock trends relative to reference points. Therefore, the state of the stock is unknown. However, the two survey-based biomass indices indicate that the exploitable biomass may be higher than at the start of the survey time-series. This can also be seen in the commercial cpue series.

## Management objectives

The management objective is to achieve sustainable fisheries. An effort management system was implemented in the Faroese demersal fisheries (Division Vb ) in 1996 and aims at harvesting, on average, $33 \%$ of the saithe stock in numbers. This translates into an average F of 0.45 , above the $\mathbf{F}_{\mathrm{pa}}$ of 0.28 . ICES considers this to be inconsistent with the Precautionary Approach.

Reference points

|  | ICES considers that: | ICES proposed that: |
| :--- | :--- | :--- |
| Precautionary Approach reference points | $\mathbf{B}_{\text {lim }}$ is 60000 t. | $\mathbf{B}_{\mathrm{pa}}$ be set at 85000 t. |
|  | $\mathbf{F}_{\text {lim }}$ is 0.40. | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.28. |

Technical basis
$\mathbf{B}_{\lim }$ : lowest observed SSB established in 1999 and corresponding to $\mathbf{B}_{\mathrm{pa}}$ : former MBAL.
SSB in 1992.
$\mathbf{F}_{\text {lim }}$ : consistent with $\mathbf{B}_{\text {lim }}$ of 60000 t .
$\mathbf{F}_{\mathrm{pa}}$ : consistent with $\mathbf{F}_{\text {lim }}$ and previous estimate
of $\mathbf{F}_{\text {med }}$.

## Single-stock exploitation boundaries

## Exploitation boundaries in relation to existing management plans

Existing management plans are inconsistent with the Precautionary Approach.
Exploitation boundaries in relation to high long-term yield, low risk of depletion of production potential and considering ecosystem effects

Long-term yield reference points are not available as there is no accepted assessment [see 2005 advice].

## Exploitation boundaries in relation to precautionary considerations

The stock cannot be evaluated with regard to PA limits. However, effort should not be allowed to increase compared to the present level. Furthermore, at landings in the range of $30-40000 \mathrm{t}$, the biomass indices have increased. With landings above this level, biomass indices are fluctuating. Therefore, ICES suggests a level of exploitation corresponding to about 40000 t . The stock seems to be sustained at a constant level in the short term.

## Conclusion on exploitation boundaries

In the absence of an agreed management plan that is consistent with the precautionary approach, ICES concludes that the exploitation boundaries for this stock should be based on the precautionary considerations.

## Management considerations

Given the uncertainties regarding stock size, the present spawning closures should be maintained.
The routine collection of information of the bycatch of saithe in the blue whiting fishery in ICES Division Vb should be undertaken. In the meantime, it is advised that sorting grids in the blue whiting fisheries become mandatory.

## Management plan evaluations

The effort management system translates to an average F of 0.45 . The management system has not been fully evaluated by ICES in relation to the defined $\mathbf{B}_{\text {lim }}$. A full evaluation should take into account the relationship between fishing mortality and fishing days.

## Ecosystem considerations

Blue whiting is a forage species for saithe. A proportion of the saithe stock is far off the shelf, probably preying on blue whiting. The blue whiting fishery thus also affects saithe by removing blue whiting.

## Factors affecting the fisheries and the stock

## Regulations and their effects

Limited measurements in the blue whiting fishery in Faroe waters indicate that bycatch of saithe may be significant.

## Changes in fishing technology and fishing patterns

Development in gear technology and optimizing fishing operations has resulted in an increase in the catchability since the early 1990s, preliminarily estimated in the order of $20 \%$ in the last decade.

## Scientific basis

## Data and methods

The commercial cpue used for stock evaluation have been standardized, taking into account season, fishing area, and boat factors. The survey biomass indices are based on stratified age-disaggregated stock in numbers multiplied by catch weight-at-age.

There are no recruitment indices available for ages younger than 3 in the terminal year. Existing research surveys may be of use in tuning, but this has not been fully evaluated.

## Comparison with previous assessment and advice

An update of previous year's assessment model was unreliable because of major reduction in growth since 1996. Because of these changes the 2005 assessment cannot be used as an indication of current status and, e.g. the yield-perrecruit cannot be used. Various probable assumptions lead to very different perceptions of the status of the stock.

The basis for the advice has consequently changed as no analytical assessment is available. The advice is now based on average catch considerations.

## Source of information

Report of the North-Western Working Group, 25 April-4 May 2006 (ICES CM 2006/ACFM:26).

| Year | ICES Advice | Predicted catch corresp. to advice | Agreed TAC | ACFM <br> Landings |
| :---: | :---: | :---: | :---: | :---: |
| 1987 | No increase in F | <32 |  | 40 |
