### 4.4.1

Advice June 2011

## ECOREGION Faroe Plateau Ecosystem <br> STOCK <br> Cod in Subdivision $\mathrm{Vb}_{1}$ (Faroe Plateau)

## Advice for 2012

ICES advises on the basis of the MSY approach to reduce fishing mortality by $30 \%$ in 2012.

## Stock status

Figure 4.4.1.1 $\quad$ Cod in Subdivision $\mathrm{Vb}_{1}$ (Faroe Plateau). Summary of stock assessment (weights in ' 000 tonnes). Top right: SSB and F over the years.

SSB has shown some increase after reaching a historical minimum in 2007, but remains below MSY $\mathrm{B}_{\text {trigger }}$. Fishing mortality has decreased since 2002 and is now between $\mathrm{F}_{\text {lim }}$ and $\mathrm{F}_{\mathrm{pa}}$, but still above $\mathrm{F}_{\mathrm{MSY}}$. The 2008 year class is estimated to be above average.

## Management plans

There is no explicit management plan for this stock.

## Biology

Recent work suggests that cannibalism is a controlling factor of recruitment. In periods with low ecosystem productivity, the individual growth of cod is slow, and some of them move into the nearshore nursery areas of 1-group cod, which hampers the recruitment of 2 -year-old cod the following year.

## Environmental influence on the stock

The productivity of the Faroe Shelf ecosystem is important to the cod stock and recruitment depends both on the stock size and on the productive state of the Faroe Shelf ecosystem. The indices of primary production have been low since 2002 except for 2004 and 2008-2010, when it was estimated to be above average.

The individual growth of cod also depends on the productivity in the outer areas of the Faroe Plateau because cod growth is highly correlated with the ratio of total phytoplankton production to total fish biomass (cod+haddock+saithe) on the Faroe Plateau, i.e. "food per fish". Phytoplankton production in the outer areas of the Faroe ecosystem (water depth $130-500 \mathrm{~m}$ ) has stayed above average since 2000.

## The fisheries

Cod are mainly taken in a directed cod and haddock fishery with longlines, in a directed jigging fishery, and as bycatch in the trawl fishery for saithe.

## Catch by fleet

Total catch $(2010)=13 \mathrm{kt}$, where $69 \%$ were taken by longlines, $13 \%$ by jigging, and $18 \%$ by trawls.

## Quality considerations

The landing data are considered accurate. There are no incentives to discard fish under the effort management system. The sampling of the landings is believed to be adequate. Estimates of F in the terminal year have varied considerably.

Figure 4.4.1.2 Cod in Subdivision $\mathrm{Vb}_{1}$ (Faroe Plateau). Historical assessment results (final year recruitment estimates included).

## Scientific basis

| Assessment type | XSA using landings-at-age data and age-disaggregated indices. |
| :--- | :--- |
| Input data | Two survey indices (spring and summer survey). |
| Discards and bycatch | There are no discard data, but discarding is not considered to be a major problem in this <br> fishery. |
|  | None. |
| Indicators | None. |
| Other information | NWWG |

## Management plan

No explicit management plan exists for this stock. A management system based on number of fishing days, closed areas and other technical measures was introduced in 1996 with the purpose of ensuring sustainable demersal fisheries in Division Vb. This was before ICES introduced PA and MSY reference values, and at the time it was believed that the purpose was achieved if the total allowable number of fishing days was set such that on average $33 \%$ of the cod exploitable stock in numbers would be harvested annually. This translates into an average F of 0.45 , above the $\mathrm{F}_{\mathrm{pa}}$ of 0.35. ICES considers this to be inconsistent with the PA and MSY approaches. Work is ongoing in the Faroes to move away from the $\mathrm{F}_{\text {target }}$ of 0.45 in order to be consistent with the ICES advice.

## MSY approach

ICES advises on the basis of the MSY approach to reduce fishing mortality by $30 \%$ in 2012 to 0.29 . This is $10 \%$ below $\mathrm{F}_{\text {MSY }}$, because SSB in 2012 is $10 \%$ below MSY $\mathrm{B}_{\text {trigger }}$.

## PA approach

The fishing mortality should be kept below an $\mathrm{F}_{\mathrm{pa}}$ of 0.35 . This translates into a reduction in fishing mortality by $15 \%$ as compared to the average of last 3 years (0.41).

## Additional considerations

## Management considerations

The present estimate of $\mathrm{F}_{\text {MSY }}$ should be regarded as provisional. Simulation studies that take the productivity of the ecosystem into account have been tried but this model is still under development.

Fishing mortalities have been well above $\mathrm{F}_{\mathrm{pa}}$ since 1996 and were estimated to be above $\mathrm{F}_{\text {lim }}$ in 2003 and 2004. Fishing mortality has declined since then but is still above $\mathrm{F}_{\mathrm{pa}}$ and should be reduced by $30 \%$ to below $\mathrm{F}_{\mathrm{MSY}}$. The SSB estimated in 2007 was the lowest in the time-series, but has since increased and is now estimated to be between $\mathrm{B}_{\text {lim }}$ and $\mathrm{B}_{\mathrm{pa}}$. Given the poor state of the Faroe haddock, measures should be taken to reduce catches of haddock while still allowing a cod fishery, e.g. closure of areas with high abundance of haddock.

One of the expected benefits of the effort management system was more stability for the fishing fleet. The fleets were expected to target the most abundant fish species, thus reducing the fishing mortality on stocks that are in bad shape. However, low prices on saithe and haddock and high prices for cod have kept the fishing mortality high on cod; the economic factors seem to be more important than the relative abundance of the stocks in determining which species is targeted. When considering future management, protection mechanisms should be included to ensure that appropriate action is taken when one or more stocks or fisheries develop in an unfavourable way.

The effort management system needs to consider changes in catchability of the fishery. For baited hook gear, catchability may be related to the amount of food available in the ecosystem. Therefore, low ecosystem production may decrease cod production and increase the catchability of longline gear. Also, the ever-increasing efficiency in an effort system needs to be carefully monitored.

## Regulations and their effects

An effort management system was implemented 1st of June 1996. Fishing days are allocated to all fleets fishing in waters $<380 \mathrm{~m}$ depth for the period 1 September-31 August. In addition the majority of the waters $<\mathrm{ca} .200 \mathrm{~m}$ depth are closed for trawling, and are mainly utilized by longliners. The main spawning areas for cod are closed for nearly all fishing gears during spawning time.

## Changes in fishing technology and fishing patterns

The effort management system triggered an improvement of fishing technology and fishing patterns. Presently, ICES is not able to quantify these changes.

## Comparison with last year's assessment and advice

The perception of the stock in this year's assessment is similar to that estimated in last year's assessment.
The advice in 2010 was to minimize haddock catches while allowing a fishery for cod. The advice this year aims to optimize cod catches according to the MSY approach.

## ECOREGION Faroe Plateau Ecosystem <br> STOCK Cod in Subdivision $\mathrm{Vb}_{2}$ (Faroe Bank)

## Advice for 2012

New data on landings and indices from the two annual Faroese surveys ( 2010 summer, 2011 spring) do not change the perception of the stock since 2008 and do not give reason to change the advice from 2010. The advice for the fishery in 2012 is therefore the same as the advice given since 2008: "Because of the very low stock size ICES advises that the fishery should be closed. Reopening the fishery should not be considered until both survey indices indicate a biomass at or above the average of the period 1996-2002".

## Management considerations

The Bank has been closed to fishing since 1 January 2009. In 2010, however, a total of 61 fishing days was allowed to small longliners ( $<15 \mathrm{BRT}$ ) in the shallow waters of the Bank.

## ECOREGION Faroe Plateau Ecosystem <br> STOCK

## Advice for 2012

ICES advises on the basis of the precautionary approach that there should be no directed fishery on haddock in 2012. Measures should be put in place to minimize bycatches of haddock in other fisheries. A recovery plan should be developed and implemented as a prerequisite to reopening the directed fishery.

Stock status

Figure 4.4.3.1 Haddock in Division Vb. Summary of stock assessment (weights in ' 000 tonnes). Top right: SSB and F over the years.

SSB has decreased since 2003 and is in 2011 estimated to be just below $\mathrm{B}_{\text {lim }}$. The fishing mortality has decreased from above $\mathrm{F}_{\text {lim }}$ in 2003 to around $\mathrm{F}_{\mathrm{pa}}$ in the last 3 years; the $\mathrm{F}_{2010}$ of 0.3 is, however, above $\mathrm{F}_{\mathrm{pa}}$. Year classes from 2003 onwards have all been well below the long-term average.

## Management plans

There is no explicit management plan for this stock.

## Biology

Since the mid-1970s, recruitment has fluctuated with 1-3 strong year classes followed by several weak ones. Mean weights-at-age have also fluctuated in this period and are at present increasing from a low level.

## Environmental influence on the stock

There is a positive relationship between primary production and the individual fish growth and recruitment 1-2 years later.

## The fisheries

Haddock are mainly caught in a directed longline fishery for cod and haddock and as bycatches in trawl fisheries for saithe. Normally, longline gears account for $80-90 \%$ of the catches. In 2009, however, (see below) longlines only accounted for $64 \%$ of the catches, primarily because only a fraction of the allocated number of fishing days to the longliners was actually used.

## Catch by fleet Total catch $(2010)=5 \mathrm{kt}$, where the longliners accounted for $79 \%$ and the trawlers for $21 \%$.

## Quality considerations

The landing data are considered accurate. There are no incentives to discard fish under the effort management system. The sampling of the landings is believed to be adequate. No major problems have been observed with the tuning indices (the two surveys).

Figure 4.4.3.2 Haddock in Division Vb. Historical assessment results (final year recruitment estimates included).

## Scientific basis

| Assessment type | XSA using age-disaggregated indices. |
| :--- | :--- |
| Input data | Two survey indices (spring and summer survey). |
| Discards and bycatch | No discards included. Discarding is not considered to be a major problem in this fishery. |
| Indicators | Primary productivity index. |
| Other information | Biomass indices from 2 commercial fleets. |

## Management plan

There is no explicit management plan for this stock. A management system based on number of fishing days, closed areas and other technical measures was introduced in 1996 to ensure sustainable demersal fisheries in Division Vb. This was before ICES introduced PA and MSY reference values, and at that time it was believed that the purpose was achieved if the total allowable number of fishing days was set such that on average $33 \%$ of the haddock exploitable stock in numbers would be harvested annually. This translates into an average F of 0.45 , above the $\mathrm{F}_{\mathrm{pa}}$ of 0.25 . ICES considers this to be inconsistent with the PA and the MSY approaches. Work is ongoing in the Faroes to move away from the $\mathrm{F}_{\text {target }}$ of 0.45 to be consistent with the ICES advice.

## MSY approach

Work is ongoing to define MSY reference points using stochastic simulations. Preliminary analyses suggested an $\mathrm{F}_{\mathrm{MSY}}=0.25$. However, historically fishing at F in this range since 1972 has led to SSB reductions to $\mathrm{B}_{\text {lim }}$ twice.

## PA approach

Given the recent poor recruitment and slow growth and the low SSB , the forecast indicates that even a zero fishing mortality in 2012 will not result in getting the stock above $\mathrm{B}_{\mathrm{pa}}$ in 2013 and there should be no directed fishery on haddock. Measures should be put in place to minimize bycatches of haddock in other fisheries. A recovery plan should be developed and implemented as a prerequisite to reopening the directed fishery.

## Additional considerations

## Management considerations

An expected benefit of the effort management system was more stability for the fishing fleet. The fleets were expected to target the most abundant fish species, thus reducing the fishing mortality on stocks that are in bad shape. This assumption is, however, not always correct; e.g. low prices on saithe and haddock and high prices for cod kept the fishing mortality higher than expected for cod. Management should include measures that avoid a disproportionate targeting of depleted stocks.

The effort management system needs to consider changes in catchability of the fishery. For baited hook gear, catchability may be related to the amount of food available in the ecosystem. Therefore, low ecosystem production may decrease haddock production and increase the catchability of longline gear. Also, the ever-increasing efficiency in an effort system needs to be carefully monitored.

An explicit management plan based on the MSY approach needs to be implemented, clearly stating what to do when the stock is very low.

## Impacts of the environment on the fish stocks

The productivity of the Faroe Shelf ecosystem is important to the haddock stock. The recruitment depends both on the spawning-stock biomass and on the productive state of the Faroe Shelf ecosystem. A positive relationship has been demonstrated between primary production and the cod and haddock individual fish growth and recruitment $1-2$ years later. The primary production indices have been above average in 2008-2010; this has, however, resulted in only marginally improved recruitment of haddock. The estimate of primary production in 2011 will not be available until July, but preliminary estimates suggest it to be lower than in 2008-2010.

## Regulations and their effects

An effort management system was implemented 1st of June 1996. Fishing days are allocated to all fleets fishing in waters $<380 \mathrm{~m}$ depth for the period 1 September-31 August. In addition, the majority of the waters $<\mathrm{ca} .200 \mathrm{~m}$ depth are closed for trawling and are mainly utilized by longliners. Some fleets (e.g. gillnetters) are presently not under the fishing days regime, but it is expected that within a few years all fleets will be included.

## Changes in fishing technology and fishing patterns

The effort management system invites improvement of fishing technology and fishing patterns. Presently, ICES is not able to quantify these changes.

## Uncertainties in assessment and forecast

Recent years have seen a consistent retrospective pattern of overestimating SSB and underestimating F. This bias seems to be small in the most recent years, however, and now the SSB has been underestimated and the F overestimated compared to the previous assessment.

The status quo assumption in the prediction may not be valid, since only a fraction of the allocated number of fishing days in recent years have actually been utilized; most of these days may become active again since the cod stock is increasing rapidly.

## Comparison with previous assessment and advice

This year's assessment indicates that the 2010 assessment overestimated the 2009 recruitment and fishing mortality by $19 \%$ and $13 \%$, respectively, and underestimated the 2009 spawning-stock biomass by $13 \%$.

The advice last year was to minimize catches of haddock. This year's advice is for no directed fishery on haddock in 2012, based on the precautionary approach.

## ECOREGION Faroe Plateau Ecosystem <br> STOCK <br> Saithe in Division Vb

## Advice for 2012

ICES advises on the basis of the MSY approach that fishing mortality in 2012 should be reduced by $38 \%$ to $\mathrm{F}_{\text {MSY }}$.

## Stock status

Figure 4.4.4.1 Saithe in Division Vb. Summary of stock assessment (weights in ' 000 tonnes). Top right: SSB and F over the years.

SSB has increased since the mid-1990s and is above MSY $\mathrm{B}_{\text {trigger }}$. Recruitment in 2010 is above average while fishing mortality is above $\mathrm{F}_{\mathrm{MSY}}$.

## Management plans

There is no explicit management plan for this stock.

## Biology

Saithe in Division Vb is regarded as one management unit although tagging experiments have demonstrated migrations between the Faroes, Iceland, Norway, west of Scotland, and the North Sea. Nursery areas for saithe are found very close to land (in the littoral zone). These areas are not covered by the existing surveys and therefore recruitment estimates are not available until saithe enter the fishery at age 3 ; this hampers the prediction of biomass and catch.

## Environmental influence on the stock

Preliminary studies suggest a positive relationship between ocean productivity (gyre index) and the biomass of saithe.

## The fisheries

Saithe are mainly caught in a directed trawl fishery (pair and single trawlers), with bycatches of cod and haddock.

## Catch by fleet Total landings (2010) $=44 \mathrm{kt}$, of which $83 \%$ was taken by pair trawlers, $12 \%$ by single trawlers,

 and $3.9 \%$ by jiggers.
## Quality considerations

There are no incentives to discard fish under the effort management system. The sampling of the landings is believed to be adequate. Recruitment indices are only available from age 3.

Figure 4.4.4.2 Saithe in Division Vb. Historical assessment results (final year recruitment estimates included).

## Scientific basis

| Assessment type | Age-based analytical assessment - XSA. |
| :--- | :--- |
| Input data | Commercial catch-at-age data and an age-disaggregated pair trawlers series. |
| Discards and bycatch | There are no discard data, but discarding is not considered to be a major problem in this <br> fishery. |
| Indicators | None. |
| Other information | A benchmark assessment was performed in 2010. |

## Management plan

There is no explicit management plan for this stock. A management system based on number of fishing days, closed areas and other technical measures was introduced in 1996 to ensure sustainable demersal fisheries in Division Vb. This was before ICES introduced PA and MSY reference values, and at that time it was believed that the purpose was achieved if the total allowable number of fishing days was set such that on average $33 \%$ of the saithe exploitable stock in numbers would be harvested annually. This translates into an average F of 0.45 , above the $\mathrm{F}_{\mathrm{pa}}$ and $\mathrm{F}_{\text {MSY }}$ of 0.28 . ICES considers this to be inconsistent with both the PA and the MSY approaches. Work is ongoing in the Faroes to move away from the $\mathrm{F}_{\text {target }}$ of 0.45 to be more consistent with the ICES advice.

## MSY approach

Following the ICES MSY framework implies that fishing mortality in 2012 should be no more than $\mathrm{F}_{\text {MSY }}=0.28$, which results in a reduction of $38 \%$ in F .

## PA approach

Following the precautionary approach implies that fishing mortality in 2012 should be no more than $\mathrm{F}_{\mathrm{pa}}=0.28$, which results in a reduction of $38 \%$ in F .

## Additional considerations

## Management considerations

ICES considers that the current fishing mortality on this stock is unlikely to result in maximum sustainable yield and should be reduced. The number of fishing days were reduced by $5 \%$ for the fishing year (2009/2010), but a further reduction of effort is required to bring F at or below $\mathrm{F}_{\mathrm{MSY}}$. This advice applies to all fleets fishing saithe, including the single trawlers that are not presently regulated by fishing days, but which have accounted for about $17 \%$ of the annual landings on average since the introduction of the present management system. The present spawning closures should be maintained.

## Regulations and their effects

The principal fleets fishing for saithe are pair trawlers, single trawlers, and jiggers. The average annual landings from these fleets since the introduction of the present management system are about $75 \%, 20 \%$ and $5 \%$, respectively. The pair trawlers and jiggers are mainly regulated by total number of allocated fishing days, whereas the single trawlers have so far mainly been regulated by the number of licenses and area closures, but not by fishing days.

Limited sampling in the blue whiting fishery in Faroese waters indicates that bycatches of saithe have been minor since the mandatory use of sorting grids from 15 April 2007 in the areas west and northwest of the Faroe Islands.

## Changes in fishing technology and fishing patterns

The effort management system implemented in 1996 is likely to lead to improvement of fishing technology. The present system offers no incentives to discard fish. The sampling of the landings is believed to be adequate.

## Comparison with last year's assessment and advice

The estimate of SSB in 2009 in the 2010 assessment was slightly higher than in the 2011 assessment and fishing mortality slightly lower.

Last year's advice was based on the precautionary approach. This year's advice is based on the MSY framework.

Table 4.4.4.1
Saithe in Division Vb. ICES advice, management, and landings.

| Year | ICES Advice | Predicted catch corresp. to advice | Agreed TAC | ICES <br> Landings |
| :---: | :---: | :---: | :---: | :---: |
| 1987 | No increase in F | $<32$ |  | 40 |
| 1988 | No increase in F | $<32$ |  | 45 |
| 1989 | Reduction in F | $<40$ |  | 44 |
| 1990 | Reduction in F | $<41$ |  | 62 |
| 1991 | TAC | <30 |  | 55 |
| 1992 | Reduction in F | $<27$ |  | 36 |
| 1993 | Reduction in F | $<37$ |  | 34 |
| 1994 | TAC | $<26$ | $42^{1}$ | 33 |
| 1995 | TAC | $<22$ | $39^{1}$ | 27 |
| 1996 | TAC | <39 | - | 20 |
| 1997 | 20\% reduction in F from 1995 level | $<21$ | - | 22 |
| 1998 | 30\% reduction in effort from 1996/97 level | - | - | 26 |
| 1999 | F below $\mathrm{F}_{\mathrm{pa}}(0.28)$ | $<14$ |  | 33 |
| 2000 | F below than $\mathrm{F}_{\mathrm{pa}}$ (0.28) | $<15$ |  | 39 |
| 2001 | Reduce fishing effort to generate F well below $\mathrm{F}_{\mathrm{pa}}$ (0.28) | $<17$ |  | 52 |
| 2002 | Reduce fishing effort to generate F below $\mathrm{F}_{\mathrm{pa}}(0.28)$ | $<28$ |  | 54 |
| 2003 | Reduce fishing effort to generate F below $\mathrm{F}_{\mathrm{pa}}(0.28)$ | $<47$ |  | 47 |
| 2004 | Reduce fishing effort to generate F below $\mathrm{F}_{\mathrm{pa}}(0.28)$ | $<48$ |  | 46 |
| 2005 | Reduce fishing effort to generate F below $\mathrm{F}_{\mathrm{pa}}(0.28)$ | <32 |  | 68 |
| 2006 | Reduce fishing effort to generate F below $\mathrm{F}_{\mathrm{pa}}(0.28)$ | <24 |  | 67 |
| 2007 | Average catch considerations | 40 |  | 61 |
| 2008 | Do not increase effort | - |  | 57 |
| 2009 | Reduce fishing effort by around 20\% | - |  | 58 |
| 2010 | Reduce fishing effort by around 20\% | - |  | 44 |
| 2011 | Reduce fishing effort to generate F below $\mathrm{F}_{\mathrm{pa}}(0.28)$ | $<38$ |  |  |
| 2012 | Reduce fishing effort to generate F below $\mathrm{F}_{\text {MSY }}(0.28)$ | $<40$ |  |  |
