## Summary

The input data consisted of the catch-at-age matrix (ages 2-10+ years) for the period 1961-2011 and two age-disaggregated abundance indices obtained from the two Faroese groundfish surveys: the spring survey 1994-2012 (shifted back to the previous year) and the summer survey 1996-2011. The maturities were obtained from the spring survey 1983-2012.
The assessment settings were the same as in the 2011 assessment. An XSA was run and tuned with the two survey indices. The fishing mortality in 2011 (average of ages 3-7 years) was estimated at 0.43 , which was higher than the preliminary Fmsy of 0.32 but lower than the limit fishing mortality (when 'bad things' may happen) of 0.68. The total stock size (age 2+) in the beginning of 2011 was estimated at 38000 tonnes and the spawning stock biomass at 24000 tonnes, which was slightly above the limit biomass (which should be avoided) of 21000 tonnes.

The short term prediction until year 2014 showed an increasing trend with a stock size in 2014 of around 38000 tonnes and a spawning stock biomass of around 23000 tonnes.

The recruitment seems to be positively correlated with the total stock size of cod. It is, therefore, advised to reduce the fishing mortality so that the stock increases.

### 4.1 Stock description and management units

Both genetic and tagging data suggest that there are three cod stocks present in Faroese waters: on the Faroe Bank, on the Faroe Plateau and on the Faroe-Iceland Ridge. Cod on the Faroe-Iceland Ridge seem to belong to the cod stock at Iceland, and the WG in 2005 decided to exclude these catches from the catch-at-age calculations. The annex provides more information.

### 4.2 Scientific data

The landing figures were obtained from the Fisheries Ministry and Statistics Faroe Islands (Table 4.2.1) and the working group estimates are presented in Table 4.2.2. The catches on the Faroe-Iceland ridge, i.e. for the large single trawlers and the large longliners were not included in the catch-at-age calculations. In recent years the longliners have taken the majority of the cod catches (Table 4.2.3). The catch-at-age was updated to account for a change in the nominal landings for 2009 and 2010. Landings-at-age for 2011 are provided for the Faroese fishery in Table 4.2.4. Faroese landings from most of the fleet categories were sampled (Table 4.2.5). Catch-at-age from 1961 to 2011 are shown in Table 4.2.6. Catch curves are shown in Fig. 4.2.1. They show atypical patterns in 1996 and to some extent in 2001-2002 when there appears to be an increase over the previous year for ages where a decrease would normally have been expected. This could be due to catchability for longliners depending on fish growth, causing atypical catch curves for longliners.

Mean weight-at-age data for 1961-2011 are provided for the Faroese fishery in Table 4.2.7. These were calculated using the length/weight relationship based on individual length/weight measurements of samples from the landings. The sum-of-productscheck for 2011 showed a discrepancy of $0 \%$.

Figure 4.2.2 shows the mean weight-at-age for 1961 to 2011. For 2012-2014 the values used in the short term predictions are shown on this graph in order to put them in perspective with previous observations. The weights were rather high for the old agegroups in 2010, but are expected to decrease..

The proportion of mature cod by age during the Faroese groundfish surveys carried out during the spawning period (March) are given in Table 4.2 .8 (1961-2011) and shown in Figure 4.2 .3 (1983-2011). The observed values in 2012 and the estimated values in 2013-2014 are also shown in order to put them in perspective with previous observations. Full maturity is generally reached at age 5 or 6 , but considerable changes have been observed in the proportion mature for younger ages between years.

The spring groundfish surveys in Faroese waters with the research vessel Magnus Heinason is used as a tuning series. The catch curves showed a normal pattern (Figure 4.2.4), i.e., a decreasing trend after age 5 . The stratified mean catch of cod per unit effort in 1994-2012 is given in Figure 4.2.5. The CPUE increased substantially in 1995 and remained high up to 1998. The CPUE decreased from 2002 to 2004, was low during 2006-2008 and a moderate increase was observed during 2009-2011. However, the 2012 value was very low. Normally the stratified mean catch per trawl hour increases for the first 3-4 years of life of a year class, and decreases afterwards (Figure 4.2.4). From 1994 to 1995, however, there was an increase for all year classes, possibly because of increased availability. A more normal pattern was observed afterwards.

The other tuning series used is the Summer Groundfish Survey. The stratified mean catch of cod per unit effort (kg/trawl hour) 1996-2011 is shown in Figure 4.2.5, and catch curves in Figure 4.2.6. The catch curves show that the fish are fully recruited to the survey gear at an age of 4 or 5 years. Both tuning series are presented in Table 4.2.9.

Two commercial cpue series (longliners and pairtrawlers) are also presented (Tables 4.2.10 and 4.2.11, as well as Figure 4.2.7), although they are not used as tuning series. This year, yet another cpue series is shown, which is the small boats ( $0-25$ GRT) operating with longlines and jigging reels close to land (Table 4.2.12).

### 4.3 Information from the fishing industry

The sampling of the catches is included in the 'scientific data'. The fishing industry has since 1996 gathered data on the size composition of the landings but this information has not been used in this assessment.

### 4.4 Methods

This is an update assessment and the results of the assessment is mostly data-driven implying that there may be limited need to use other assessment methods.

### 4.5 Reference points

The reference points are dealt with in the general section of Faroese stocks. The PA reference points for Faroe Plateau cod are the following: $\mathrm{B}_{\mathrm{pa}}=40 \mathrm{kt}$, $\mathrm{Blim}_{\mathrm{lim}}=21 \mathrm{kt}, \mathrm{F}_{\mathrm{pa}}=$ 0.35 and $\mathrm{F}_{\mathrm{lim}}=0.68$.

The reference points based on the yield-per-recruit curve are the following: $\mathrm{F}_{\max }=$ $0.25, \mathrm{~F}_{0.1}=0.11, \mathrm{~F} 35 \% \mathrm{SPR}=0.17, \mathrm{~F}_{\text {med }}=0.41, \mathrm{~F}_{\text {low }}=0.10, \mathrm{~F}_{\text {high }}=0.97$.

The group adopted in 2011 following preliminary MSY reference points: $\mathrm{F}_{\mathrm{msy}}=0.32$,

### 4.6 State of the stock - historical and compared to what is now

Since the current assessment is an update assessment, the same procedure is followed as in the 2011 assessment: to use the two surveys for tuning and not the commercial series. The commercial series showed a similar overall tendency as the surveys (Figure 4.2.7). The XSA-run is presented in Table 4.6.1 and the results are shown in Table 4.6.2 (fishing mortality at age), Table 4.6 .3 (population numbers at age) and Table 4.6.4 (summary table).

The log catchability residuals from the adopted XSA run are shown in Figure 4.6.1. There were year effects in both surveys since 2005. The stock estimates for 2011 seemed to be determined more by the summer survey than the spring survey.

The estimated fishing mortalities are shown in Tables 4.6.2 and 4.6.4 and Figures 4.6.2 and 4.6.3. The average F for age groups 3 to 7 in 2011 (F3-7) is estimated at 0.43 , somewhat higher than $\mathrm{F}_{\mathrm{pa}}=0.35$.

The F3-7 (Figure 4.6.3) seems to be a problematic measure of fishing mortality for two reasons. Firstly, the fishing mortalities for ages 6-7 are generally overestimated in the terminal year leading to an overestimation of F3-7 for the terminal year. Secondly, the proportion of 6-7 year old cod in the stock or catch is small (normally less than $20 \%$ ) and therefore get a disproportionate influence on the F3-7. The yield over exploitable biomass (3 years and older) was introduced in the 2004 assessment, but has the drawback not being proportional to fishing effort. Another approach is to weight the fishing mortalities, and three weighting procedures are presented in Figure 4.6.4: weighting by stock numbers, stock biomasses or catch weights. The fishing mortality may have increased slightly since 1996, but there have been oscillations that may be determined by the food availability in the ecosystem.

The stock size in numbers is given in Table 4.6.3. A summary of the XSA, with recruitment, biomass and fishing mortality estimates is given in Table 4.6.4 and in Figure 4.6.2. The stock-recruitment relationship is presented in Figure 4.6.5. The stock trajectory with respect to existing reference points is illustrated in Figure 4.6.6.
The assessment shows the poor recruitment for the 1984 to 1991 year classes, and the strong 1992 and 1993 year classes. Due to the continuous poor recruitment from 1984 to 1991 and the high fishing mortalities, the spawning stock biomass declined steadily from 1983 to 1992 when it was the lowest on record at 21000 t . It increased sharply to above 80000 t in 1996 and 1997 before declining to about 45000 t in 1999. The spawning stock biomass increased to 59000 t in 2001 but dropped to about 18000 t in 2007 which is the lowest value observed during the assessment period from 1961 to 2011. The 2002 year class is likely the lowest observed and the 2003-2006 year classes are also weak according to the XSA run. The 2007 year class seems to be at bit stronger ( 10 millions), and the 2008 year class seems to be of average strength ( 15 mil lions). The 2009 year class is estimated at only 4 million individuals. The 2010 year class is in the XSA run estimated at the extremely low value of 0.07 millions, but this estimate relies solely on the spring survey estimate in 2012 (shifted to 2011 in the tuning). This value was adjusted to about 7 millions (see section 4.7).

In order to put the stock estimates in 2011 into a wider perspective, we have estimated the stock biomass back to 1906. A cpue series (tonnes per million tonn-hours) for British trawlers 1924-1972 was available from the data presented in Jákupsstovu
and Reinert (1994). The cpue series was also used, and explained, in Jones (1966). There was an overlap between the cpue series and the stock assessment for the years 1961-1972. Another cpue series (cwts per day of absence from port, $1 \mathrm{cwt}=50.8 \mathrm{~kg}$ ) was available for British steam trawlers 1906-1925. The overlap was two years (1924 and 1925) and the 1906-1925 series was scaled to the 1924-1972 series. The results are presented in Figure 4.6.7. There was a decreasing trend in biomass from around 100 thousand tonnes to around 80 tonnes prior to World War II, and since then a decreasing trend from around 100 thousand tonnes to around 50 thousand tonnes. The biomass in 2011 was very low compared with the entire period.

### 4.7 Short term forecast

The input data for the short term prediction are given in Table 4.7.1. Considerable uncertainty was associated with the strength of the 2010 year class. The adopted figure was to use the lowest observed value of 3.7 million. Another candidate was 6.84 millions. The value was obtained from a regression between $\log (B / C)$ and recruitment, where " B " is the age $3+$ biomass in the recruitment year and " C " is the biomass of predatory age $3+$ biomass close to land the year before the recruitment year (Figure 4.7.1, Figure 4.7.2). " C " was itself obtained from a regression between age $3+$ biomass on the Faroe Plateau and the condition factor of cod within the 120 m contour (low condition factor: higher proportion close to land), see also Steingrund et al., 2010 and Steingrund, 2012 NWWG WD 31. The strength of the 2011 and 2012 year classes was set at the average of yc 2007 to yc 2009. If the procedure in the Annex is followed (the 2010 year class $=$ the XSA value of 0.066 millions (Table 4.7.3)), a pessimistic forecast is obtained (spawning biomass in $2014=35000 \mathrm{t}$ (Table 4.7.4) compared with 40000 t (Table 4.7.2)). Estimates of stock size (ages 3+) were taken directly from the XSA stock numbers. The exploitation pattern was estimated as the average fishing mortality for 2009-2011. The weights at age in the catches in 2012 were estimated from the commercial catches in January-February or the spring survey (ages 2 and $4-6$ years). The weights in the catches in 2013 were set to the values in 2012, i.e., rather high values, whereas a lower value (average 2010-2012) was expected in 2014. The proportion mature in 2012 was set to the 2012 values from the spring groundfish survey, and for 2013-2014 to the average values for 2010-2012.

Table 4.7.2 shows that the landings in 2012 are expected to be 11000 tonnes (the landings from the Faroe-Icelandic ridge should be added to this figure in order to get the total Faroese landings within the Vb 1 area). The spawning stock biomass is expected to be 26000 tonnes in 2012, 23000 tonnes in 2013 and eventually 23000 tonnes in 2014. The current short term prediction is therefore somewhat pessimistic. The contribution of the various year-classes to the SSB in 2013 and 2014 is shown in Figure 4.7.3. It shows that the incoming year-classes (YC 2008-YC 2011) dominate the SSB.

A short term projection using the Annex procedures is presented in Table 4.7.3 and Table 4.7.4. It shows that the SSB in $2014(20000 \mathrm{t})$ will be below $\mathrm{B}_{\lim }$ of 21000 t .

### 4.8 Long term forecast

The input to the traditional long term forecast is presented in Table 4.8.1 and the result is presented in Table 4.8.2 and Figure 4.8.1.

Single species long term forecasts for Faroe Plateau cod indicated $\mathrm{F}_{\text {msy }}$ values lower than $\mathrm{F}_{\text {pa. }}$. An FLR procedure (MSE, Management strategy evaluations using FLR standard packages; a simulation of management and stock response over a 20 yr period)
for Faroe Plateau cod indicates that $\mathrm{F}_{\text {msy }}$ is 0.32 . This value ( 0.32 ) was adopted by the group as a preliminary $\mathrm{F}_{\mathrm{msy}}$.

Multispecies models may give very different perception of Fmsy reference points than single-species models. Therefore, a long-term simulation was performed in 2011 NWWG report to evaluate MSY reference points for cod, haddock and saithe, all in the same ecological model (see Steingrund et al., 2011NWWG WD 22). The model settings and the results were presented in the Overview section for the Faroese stocks.

The ecological model was driven by 1) yearly primary production on the Faroe Shelf (<130 m bottom depth), 2) yearly primary production over the outer areas on the Faroe Plateau (130-500 m bottom depth), as well as the fishing mortality of 3) cod, 4) haddock and 5) saithe. The recruitment of saithe, being positively affected by the primary production over the outer areas on the Faroe Plateau and negatively affected by the age $7+$ biomass of saithe had a very large influence on the results. For example, when fishing mortality of saithe increased, the age 7+ biomass decreased, which increased the saithe recruitment and biomass. A higher biomass of saithe led to a decrease the condition factor of cod, and hence a decrease of cod recruitment.

Recent work (Steingrund et al., 2012), however, indicates that another ecological model may be more appropriate. There is a moderate positive correlation between primary production on the Faroe Shelf and the subsequent production of cod (Steingrund and Gaard, 2005). There is also a moderate positive correlation for haddock and saithe. However, if all three species are combined, the positive correlation becomes very strong. This indicates that a nearly fixed portion of the energy produced by the primary production goes to predatory demersal fish on the Faroe Plateau, but that the portion to each of the fish species (to cod, haddock or to saithe) may vary much between years. For example, the portion to saithe varied between 30 and $80 \%$ between 1961 and 2008, and was high when sandeels were scarce. Surprisingly, the fit between primary production and cod+haddock+saithe production was not improved by including the outer primary production, i.e., this ecological model is simpler than the former one with regards to primary production. On the other hand, other variables needed to be included in the model, for example the influx of Calanus finmarchicus onto the Faroe Shelf. It is hoped that the ecological model work can be done with sufficient pace to be included in future NWWG reports.

The fishing mortality in 2008-2011 (0.50) has been above the preliminary $\mathrm{F}_{\mathrm{msy}}$ of 0.33 . The lower fishing mortality for 2011 (0.43) may be a result of area closures introduced in July 2012. The closure of the nearshore areas for commercial longliners, as well as other areas (for all fishing) (see Figure in overview section for Faroese stocks), were initiated to protect the 2008 and 2009 year classes. The 2008 year class was in the last year's report regarded to be above average size, but is now considered of average size. Figures 4.8 .2 and 4.8 .3 show the average abundance of 2 - and 4 -years old cod in March (1994-2012) and August (1996-2011).

### 4.9 Uncertainties in assessment and forecast

The results from the retrospective analysis of the XSA (Figure 4.9.1) show that there has been a tendency to overestimate recruitment, underestimate total stock/spawning stock biomasses, and to overestimate the fishing mortality. However, the revision of biomasses and fishing mortality from 2010 to 2011 (terminal year) is in the opposite way: decreasing biomasses and increasing $F$.

Misreporting is not believed to be a problem under the current effort management system. The total catch figures (in sub-divisions $\mathrm{Vb} 1+\mathrm{Vb} 2$ ) are believed to be accurate, although there may be some minor problems when allocating the catches between the two sub-divisions.

The sampling of the catches for length measurements and length-weight relationships is considered to be adequate but the number of otoliths could be higher.
The quality of the tuning data is considered to be adequate. The same research vessel has been used all the time and the gear as well as sampling procedures of the catch have remained the same. The only exception may be the otolith sampling during 1994-1996 when larger otolith samples were collected from fewer hauls than during the other years (1997 to present). There was a good agreement between the survey indices and when compared to the commercial tuning series.

### 4.10 Comparison with previous assessment and forecast

The assessment settings were according to the Annex. Unfortunately, the settings last year were, by mistake, slightly different, compared with the Annex: the catchability was not regarded independent of stock size for all ages, but only for ages 3+. Rerunning the 2011 assessment according to the Annex gave a higher 2008 year class (by 4 millions) and a lower 2009 year class (by 4 millions), influencing total stock biomass positively (by 4 thousand tonnes), but nearly not spawning stock biomass and fishing mortality. The estimates of the incoming year classes in the short term projection were obtained in a slightly different way (see section 4.7) than described in the Annex. The Annex procedure estimated the strength of the 2010 year class to be 0.081 millions at age 1 (Figure 4.9.1), corresponding to 0.066 millions at age 2, whereas the alternative procedure gave 6.8 millions at age 2 .

Recruitment, total stock biomass, spawning stock biomass in 2010 and 2011 were estimated lower in the current assessment compared to what was estimated/predicted last year, whereas the fishing mortality was higher (Table 4.10.1).

### 4.11 Management plans and evaluations

There is no explicit management plan for this stock. A management system based on number of fishing days, closed areas and other technical measures was introduced in 1996 with the purpose to ensuring sustainable demersal fisheries in Vb. This was before ICES introduced PA and MSY reference values and at the time it was believed that the purpose was achieved, if the total allowable number of fishing days was set such, that on average $33 \%$ of the cod exploitable stock in numbers would be harvested annually. This translates into an average F of 0.45 , above the $\mathrm{F}_{\mathrm{pa}}$ of 0.35 . ICES considers this to be inconsistent with the PA and MSY approaches. Work is ongoing in the Faroes to move away from the Ftarget of 0.45 to be more consistent with the ICES advice.

### 4.12 Management considerations

The current assessment shows that the spawning cod stock was below Blim of 21000 tonnes in 2007-2008, and will likely stay slightly above Blim the next two years. The primary production was high in 2008-2010, but decreased to below-average in 2011. If the development over time in the primary production, usually oscillating between above-average periods and below-average periods, continues in the near future, the
primary production will stay low during 2012-2013. This will likely prevent a recovery of the cod stock in the near future.

Biomass estimates of Faroe Plateau cod reconstructed back in time (Figure 4.6.7) show that the biomass fluctuated around 100000 tonnes during the period 1906-1957, around 80000 tonnes during 1958-1987 and eventually around 60000 tonnes since 1988. The catches fluctuated between 20000 and 40000 tonnes, except in 1990-1994 and 2004-2010 when they fluctuated around 10000 tonnes. Similar catches from smaller biomasses imply that the exploitation rates have increased over time.

There has been a long held view on the Faroe Islands that the cod stock is very resilient to exploitation and that a collapse in the fishery is nearly impossible - people bear in mind the rapid recovery of the cod stock during 1994-1996. The collapse in the fisheries during 1991-1994 has been regarded as an exceptional event. Figure 4.6.7 indicates that, although more resilient than some other cod stocks in the North Atlantic, Faroe Plateau cod does show a decreasing trend since World War II. This trend is likely caused by a combination of environmental factors and fishing effort, but there are reasons to believe that the fishing effort has increased during the period.

The catchability hypothesis presented in the overview section for Faroese stocks, see the report in 2009 (ICES, 2009), states that the fishing mortality is high when the primary production is low and vice versa. The primary production was low, or average, during 2002-2007 and the high fishing mortalities in 2002-2005 were therefore not unexpected. The primary production in 2008 to 2010 was above average, but below average in 2011, and is expected to stay so some years to come. Hence, it is expected that the fishing mortality will increase in 2011 and onwards. This might pull the fishing mortalities upwards whereas the area closures introduced in 2011 may act in the opposite way.

A note on nominal and actual fishing days is worthwhile. The assessment F provides the result of the actual fishing days used at sea, and the simulations providing Fmsy, as well as reductions in F (by e.g. 35\%), apply to the actual fishing days used. One reason why the fishing mortality has been so low the last years is the fact that as many as $40 \%$ of the nominal fishing days have not been used. Hence, in order to obtain the maximal sustainable yield in the future, the nominal fishing days have to be reduced considerably more than the actual fishing days.
Up to $40 \%$ of the allocated days have not been used the last 3-4 years, which may have contributed to the comparatively low fishing mortality. However, these unutilized fishing days seem to represent a major obstacle in rebuilding the cod stock to levels where it is able to produce the maximum long-term yield, because they will likely be activated when more cod can be fished. The number of un-utilized fishing days is largest for the small boats (less than half of the days used) (see Overview section for Faroese stocks).

### 4.13 Ecosystem considerations

The effects of the cod-fishery on the ecosystem (e.g. damage on the bottom) are expected to be small since the majority of the cod catch is taken by longlines. Regarding the ecosystem effects on fishing, this issue is partly addressed in the ecological modelling work presented in the Overview section for Faroese stocks.

### 4.14 Regulations and their effects

As mentioned earlier, there seems to be a poor relationship between the number of fishing days and the fishing mortality because of large fluctuations in catchability. Area restrictions may help to reduce fishing mortality, but they cause practical problems for the fishing fleets (e.g. high concentrations of vessels in certain areas). Area restrictions may be best suited to protect certain fish species/sizes in certain areas, whereas the number of fishing days remains the only tool to reduce the overall fishing mortality.

### 4.15 Changes in fishing technology and fishing patterns

Fishing effort per fishing day may have increased gradually since the effort management system was introduced in 1996, although little direct quantitative information exists. There also seems to have been substantial increases in fishing power when new vessels are replacing old vessels.

The fishing pattern in 2006-2011 has changed in comparison to previous years. The large longliners seem to have exploited the deep areas ( $>200 \mathrm{~m}$ ) to a larger extent (ling and tusk) because the catches in shallower waters of cod and haddock have been so poor - which was also observed in the beginning of the 1990s. This could reduce the fishing mortality on cod and haddock, but the small longliners still exploit the shallow areas.

### 4.16 Changes in the environment

The primary production has been low for a number of years, albeit high in 2008 to 2010, but it is not believed that this has any relationship with a change in the environment.

Table 4.2.2. Faroe Plateau cod (sub-division Vb1). Nominal catch (tonnes) of COD in sub-division Vb1 (Faroe Plateau) 1986-2010, as used in the assessment.

Table 4.2.3. Faroe Plateau cod (sub-division Vb 1 ). The landings of Faroese fleets (in percents) of total catch. Note that the catches on the Faroe-Iceland ridge (mainly belonging to single trawlers > 1000 HP ) are included in this table, but excluded in the XSA-run.

Time series weights :

Tapered time weighting not applied
Catchability analysis :
Catchability independent of stock size for all ages

Catchability independent of age for ages >= 6
Terminal population estimation :
Survivor estimates shrunk towards the mean $F$
of the final 5 years or the 5 oldest ages.
S.E. of the mean to which the estimates are shrunk $=2.000$

Minimum standard error for population
estimates derived from each fleet $=$. 300
Prior weighting not applied
Tuning converged after 29 iterations

| Spawning stock biomass | 39754 | 23813 | -40 |
| Fishing mortality | 0.4114 | 0.4326 | 5 |

## Annex

| Variable | Assm. 2011 | Assm. 2012 | Change\% |
| :--- | :--- | :--- | :--- |
| Year | 2011 | 2011 |  |
| Recruitment | 10200 | 4400 | -57 |
| Total stock biomass | 51618 | 38344 | -26 |
| Spawning stock biomass | 29801 | 23813 | -20 |
| Fishing mortality | 0.4114 | 0.4326 | 5 |

Figure 4.2.1. Faroe Plateau cod (sub-division Vb 1 ). Catch in numbers at age shown as catch curves.

Figure 4.2.2. Faroe Plateau cod (sub-division Vb1). Mean weight at age 1961-2011. The estimated weights in 2012 are also shown. The weights in 2013 are set to the 2012 values. The weights in 2014 are set to the average values for 2010-2012.

Figure 4.2.3. Faroe Plateau cod (sub-division Vb1). Proportion mature at age as observed in the spring groundfish survey. The values in 2013 and 2014 are estimated as the average of the 20102012 values.

Figure 4.2.4. Faroe Plateau cod (sub-division Vb1). Catch curves from the spring groundfish survey.

Faroe Plateau cod

Figure 4.2.5. Faroe Plateau cod (sub-division Vb1). Stratified kg/hour in the spring and summer surveys. The age $3+$ biomass obtained from the assessment is also included as an index.

Figure 4.2.6. Faroe Plateau cod (sub-division Vb1). Catch curves from the summer groundfish survey.

Figure 4.2.7. Faroe Plateau cod (sub-division Vb1). Standardised catch per unit effort for pair trawlers and longliners. The two surveys are shown as well.

## Spring survey (shifted back to December)

## Summer survey

Figure 4.6.1. Faroe Plateau cod (sub-division Vb1). Log catchability residuals for the spring and summer survey. The residuals for age 8 are not presented because some values were off scale. White bubbles indicate negative residuals.

Spawning stock and recruitment

Yield and fishing mortality

Figure 4.6.2. Faroe Plateau cod (sub-division Vb1). Yield and fishing versus year. Spawning stock biomass (SSB) and recruitment (year class) versus year. Points (white and grey) are taken from the short term projections.

Figure 4.6.3. Faroe Plateau cod (sub-division Vb1). Fishing mortalities by age. The F-values in 2012-2014 are set to the average values in 2009-2011.

## Faroe Plateau cod

Figure 4.6.4. Faroe Plateau cod (sub-division Vb1). Different measures of fishing mortality: straight arithmetic average (Avg F), weighted by stock numbers (Nwtd), weighted by stock biomass (Bwtd) or weighted by catch (Cwtd).

Figure 4.6.5. Faroe Plateau cod (sub-division Vb1). Spawning stock - recruitment relationship 1961-2009. Years are shown at each data point.

## Precautionary Approach Plot

Period 1961-2012

Figure 4.6.6. Faroe Plateau cod (sub-division Vb1). Spawning stock biomass versus fishing mortality 1961-2012.

Figure 4.6.7. Faroe Plateau cod (sub-division Vb1). Stock development 1906-2010 based on cpues from british steam trawlers (1906-1925: cwts per days of absence from port), cpues from british trawlers (1924-1972: tonnes per million tonn hours) and the XSA-estimates (1961-2010: absolute biomass). The 1906-1925 series was scaled to the 1924-1972 series and the CPUEs refer to the first (left) axis while the XSA-estimates refer to the second axis.

Faroe Plateau cod recruitment, models fitted for 1997-2008

$$
\rightarrow \text { Observed from XSA } \rightarrow-\text { Predicted from B3+/C }- \text { Predicted from B3+/C and CPUE Norway pout }
$$

Figure 4.7.1. Faroe Plateau cod (sub-division Vb1). Modelling cod recruitment from the amount of cannibalistic nearshore cod $(C)$ and age $3+$ biomass ( $B 3+$ ) ( $R$-square $=0.88$ ), as well as when CPUE of Norway pout in the March survey was included in the model (adjusted R-square $=0.94$ ). Note that both models give quite similar results for the recruitment in 2011 and 2012, which are higher than the estimates from the XSA run.

Faroe Plateau cod, recruitment estimates based on longline and trawl data

Faroe Plateau cod, recruitment indices (set to age 2) based on bycatch in Norway
lobster pods

Figure 4.7.2. Faroe Plateau cod (sub-division Vb1). Recruitment estimates based on longline and trawl data already presented in the two figures before (upper panel). The lower panel shows the bycatch of juvenile cod in nearshore Norway lobster pods, and the data are shifted in such a way that they correspond to the recruitment at age 2. The recruitment in 2012 was estimated as the average of the values obtained from the ' $B 3+x$ deep fish' model and the ' $B 3+/ C^{\prime}$ model.

Figure 4.7.3. Faroe Plateau cod (sub-division Vb1). Contribution of various year classes to the spawning stock biomass in 2013 and 2014.
