## ECOREGION Faroe Plateau ecosystem <br> STOCK Haddock in Division Vb

## Advice for 2013

ICES advises that there should be no directed fishery on haddock in 2013. Measures should be put in place to minimize by-catches of haddock in other fisheries. A recovery plan should be developed and implemented as a prerequisite to reopening the directed fishery.

## Stock status

Figure 4.4.3.1 Haddock in Division Vb. Summary of stock assessment (weights in thousand tonnes). Top right: SSB/F for the time-series used in the assessment.

SSB has decreased since 2003 and in 2012 it is estimated to be below $\mathrm{B}_{\text {limm }}$. The fishing mortality has decreased from above $\mathrm{F}_{\text {lim }}$ in 2003 to just above $\mathrm{F}_{\text {MSY }}$ for the last 3 years. Year classes from 2003 onwards have all been well below the long-term average.

## Management plans

A group representing the Ministry of Fisheries, the Faroese industry, the University of the Faroe Islands, and the Faroe Marine Research Institute has developed a management plan based on general maximum sustainable yield (MSY) principles developed by ICES. The plan has not yet been discussed by the political system.

## Biology

Since the mid-1970s, recruitment has fluctuated with 1-3 strong year classes followed by several weak to moderate ones. Mean weights-at-age have also fluctuated in this period.

## Environmental influence on the stock

A positive relationship has been documented between primary production and the individual fish growth and recruitment 1-2 years later.

## The fisheries

Haddock are mainly caught in a directed longline fishery for cod and haddock and as by-catches in trawl fisheries for saithe. Normally, longline gears account for $80-90 \%$ of the catches. In 2011 longlines accounted for $82 \%$ of the catches.

Catch distribution Total landings (2011) are 3.5 kt , where longliners accounted for $82 \%$ and trawlers for $18 \%$. No discards and no unaccounted removals.

## Quality considerations

The landings data are considered accurate. There are no incentives to discard fish under the effort management system. The sampling of the landings is believed to be adequate. No major problems have been observed with the tuning indices (the two surveys).

## Management plan

A management system based on number of fishing days, closed areas, and other technical measures was introduced in 1996 to ensure sustainable demersal fisheries in Division Vb. This was before ICES introduced precautionary approach (PA) and MSY reference values, and at that time it was believed that the purpose was achieved if the total allowable number of fishing days was set such that on average $33 \%$ of the haddock exploitable stock in numbers would be harvested annually. This translates into an average F of 0.45 , above the $\mathrm{F}_{\mathrm{pa}}$ and $\mathrm{F}_{\text {MSY }}$ of 0.25 . ICES considers this to be inconsistent with the PA and the MSY approaches. Work is ongoing in the Faroes to move away from the $\mathrm{F}_{\text {target }}$ of 0.45 to be consistent with the ICES advice. This management plan includes a stepwise reduction of the fishing mortality to $\mathrm{F}_{\text {MSY }}$ in 2015 and a recovery plan if the SSB declines below the MSY $\mathrm{B}_{\text {trigger. }}$. The MSY $\mathrm{B}_{\text {trigger }}$ has been defined at 35 kt (the former $\mathrm{B}_{\mathrm{pa}}$ ) and $\mathrm{F}_{\text {MSY }}$ at 0.25 . If the SSB declines below the MSY $\mathrm{B}_{\text {trigger }}$, the fishing mortality will be reduced by the relationship $\mathrm{F}_{\text {MSY }} * B_{\text {act }} /$ MSY $B_{\text {trigger }}$ until the SSB has increased again above the MSY $B_{\text {triger }}$ and is thereafter kept at $\mathrm{F}_{\text {MSY }}$.

## MSY approach

Based on stochastic simulations MSY preliminary analyses suggested an $\mathrm{F}_{\text {MSY }}=0.25$. Work is still needed to confirm these analyses. Using this $\mathrm{F}_{\text {MSY }}$ value and given that SSB in 2013 is estimated below MSY $\mathrm{B}_{\text {trigger }}$, fishing mortality should be reduced further. F in 2013 should be no more than $\mathrm{F}_{\mathrm{MSY}} * \mathrm{~B}_{2013} / \mathrm{MSY} \mathrm{B}_{\text {trigger }}=0.15$.

## Precautionary approach

Given the recent poor recruitment and slow growth and the low SSB, the forecast indicates that even a zero fishing mortality in 2013 will not result in getting the stock above $\mathrm{B}_{\mathrm{lim}}$ in 2014. There should therefore be no directed fishery on haddock. Measures should be put in place to minimize bycatches of haddock in other fisheries. A recovery plan should be developed and implemented as a prerequisite to reopening the directed fishery.

## Additional considerations

## Management considerations

An expected benefit of the effort management system was more stability for the fishing fleet. The fleets were expected to target the most abundant fish species, thus reducing the fishing mortality on stocks that are in bad shape. This assumption is, however, not always correct; e.g. low prices for saithe and haddock and high prices for cod kept the fishing mortality higher than expected for cod. Management should include measures that avoid a disproportionate targeting of depleted stocks.

The effort management system needs to consider changes in catchability of the fishery. For baited hook gear, catchability may be related to the amount of food available in the ecosystem. Therefore, low ecosystem production may decrease haddock production and increase the catchability of longline gear.

An explicit management plan based on the MSY approach needs to be implemented, clearly stating what to do when the stock is very low.

In recent years only a fraction of the allocated number of fishing days has actually been utilized.

## Impacts of the environment on the fish stocks

The productivity of the Faroe Shelf ecosystem is important to the haddock stock. The recruitment depends both on the spawning-stock biomass and on the productive state of the Faroe Shelf ecosystem. A positive relationship has been demonstrated between primary production and the cod and haddock individual fish growth and recruitment $1-2$ years later. The primary production indices were above average in 2008-2010; however, this has resulted in only marginally improved recruitment of haddock.

## Regulations and their effects

An effort management system was implemented 1 June 1996. Fishing days are allocated to all fleets fishing in waters $<380 \mathrm{~m}$ depth for the period 1 September-31 August. In addition, the majority of the waters < ca. 200 m depth are closed to trawlers and are mainly utilized by longliners.

## Changes in fishing technology and fishing patterns

The effort management system can lead to improvement of fishing technology efficiency. Presently, ICES is not able to quantify these changes.

## Uncertainties in assessment and forecast

Recent years have revealed a consistent retrospective pattern of overestimating SSB and underestimating F. This bias seems to be small in the most recent years, however.

## Comparison with previous assessment and advice

This year's assessment shows that the 2011 assessment overestimated the 2010 recruitment by around $30 \%$, underestimated the fishing mortality in 2010 by $8 \%$, and overestimated the 2010 total and spawning-stock biomasses by $15 \%$ and $12 \%$, respectively.

The advice last year was for no directed fishery on haddock in 2012, based on the precautionary approach, and to minimize bycatches in other fisheries. This year's advice is based on the MSY approach.
